- 15 Abstract

9

11

- Purpose: This study investigates the feasibility, effectiveness, and patient response to using
- Mixed Reality (MR) technology, specifically the HoloLens, for preoperative education in
- 18 patients requiring pancreatoduodenectomy. It aims to determine if MR improves patient
- understanding, comfort, and comprehension during informed consent compared to traditional
- 20 methods.
- 21 Methods: A single center randomized controlled pilot study was conducted with patients
- 22 recommended for pancreatoduodenectomy due to pancreatic mass between February and May
- 23 2023. Exclusion criteria included age under 18, lack of English fluency, or severe visual/hearing

impairments. Participants completed pre- and post-intervention surveys assessing their 24 understanding of their condition and care. The control group received standard education, while 25 the intervention group used the HoloLens. 26 Results: Nineteen patients participated, with eight in the HoloLens group. Both groups showed 27 improved understanding post-intervention, but only the HoloLens group had a statistically 28 29 significant increase in overall comprehension (Z=-2.524, p=0.012). The HoloLens group also had a significant improvement in understanding surgical steps and other aspects compared to 30 controls. High comfort levels with the planned surgery were reported by 75% of participants in 31 both groups. 32 Conclusions: MR technology, such as the HoloLens, can significantly enhance patient 33 understanding and comfort in preoperative education for complex surgeries. Its integration into 34 clinical practice was feasible and non-disruptive, suggesting broader applicability. The small 35 sample size and single-center design limit generalizability, necessitating larger studies to confirm 36 these findings and assess the full impact of MR on patient surgical education. 37

### Introduction

Over 8,000 pancreatoduodenectomies are performed annually in the United States with a morbidity rate >50% [1]. Given the ubiquity and potential severity of complications, it is imperative that patients understand their disease and its management. Unfortunately, verbal descriptions and basic visual illustrations are poorly understood by patients [2].

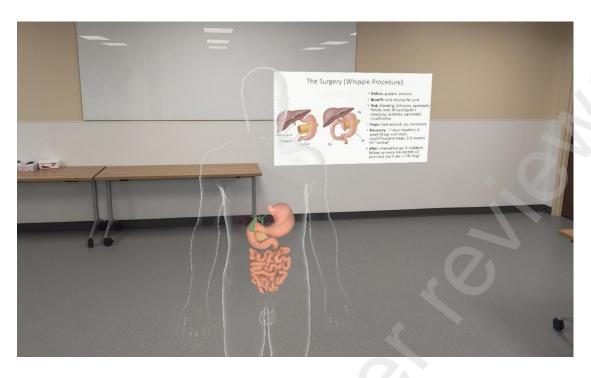

Extended reality (XR) (virtual, augmented, mixed) devices have recently achieved a novel role within medical education. HoloAnatomy (Case Western Reserve University, Cleveland, OH), available on the HoloLens 2 (Microsoft Corp., Redmond, WA) platform, allows users to visualize a holographic, 3D human model displaying selected organs of interest and presentations while the user's physical surroundings remain visible. HoloAnatomy's teacher-student function provides an interactive learning session for multiple users simultaneously and has been shown to increase long-term information retention among medical students compared to standard instruction alone [3].

Despite the growing role of XR within medical education, there has been an extreme paucity of inquiry into its use in direct patient education. Particularly with respect to informed surgical consent. This study aims to explore the feasibility, effectiveness, and patient response to the use of HoloLens during pancreatoduodenectomy informed consent discussions.

# **Materials and Methods**

This is a single-center, prospective, IRB-approved, randomized pilot study of patients offered a pancreatoduodenectomy secondary to a pancreatic mass between February and May of 2023. Patients were excluded if they were <18 years old, lacked English fluency, or had severe visual or hearing impairments.

Participants completed a pre-intervention survey assessing their date of tumor diagnosis, age, sex, education level, and number of support members present during the visit. A 5-point Likert scale evaluated the patient's perceived understanding regarding their diagnosis and various aspects of their care. The control group received a standard discussion regarding pancreatoduodenectomy accompanied by physician-drawn diagrams. The intervention group received the same discussion while using the Mixed Reality (MR) device (Figure 1).

**Figure 1.** The patient visual experience while using the HoloLens device. A presentation is presented in the background while the holographic anatomy allows for an interactive patient experience.

A post-intervention survey of the same, but re-ordered, 5-point Likert scale questions plus an additional question about the patient's comfort level with surgery was completed.

Data were non-parametric. Comparisons between groups were performed by Mann-Whitney U and related-samples Wilcoxon signed rank tests using SPSS for Macintosh, Version 28.0 (IBM Corp., Armonk, NY).

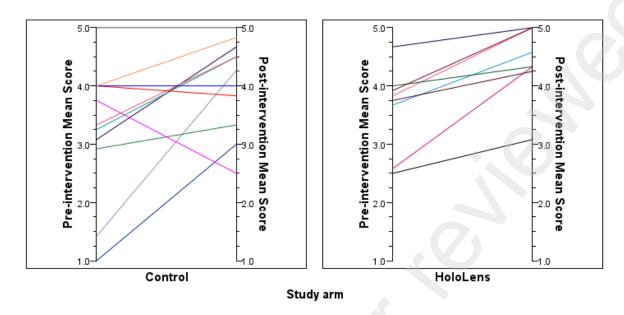

# Results

Nineteen patients were included (89.4% participation) with 8 patients assigned to the HoloLens arm. The median age was 67 (IQR 12) years with controls tending to be younger (64 vs 69 years, p= 0.181). Twenty-four days was the median time between diagnosis and

randomization. All but 5 patients had a post-high school degree with education levels well distributed between groups (Table 1).

Table 1. Highest leve           patient		
	Co	unts
Education level	Control	HoloLens
High school	3	2
Trade school	1	1
Bachelor's degree	4	4
Master's degree	3	0
Doctorate	0	1

Table 2 provides detailed survey results and Figure 2 provides a visual depiction of the pre- and post-intervention survey results. There was no difference between overall pre- or post-intervention survey totals between cohorts. The median pre-intervention score for the controls was 40.0 (mean response 3.3), while the HoloLens median score was 45.5 (mean response 3.6) (U= 49.0, p= 0.678). The post-intervention surveys revealed a median total score of 51.0 (mean response 4.0) and 53.5 (mean response 4.4) for the control and HoloLens cohorts, respectively (U= 59.0, p= 0.213). While the post-intervention survey results were grossly improved for both study arms, specifically HoloLens patients showed improvement in overall pre- and post-intervention results (Z= -2.524, p= 0.012).

**Figure 2.** Comparison of the relationship between mean pre- and post-intervention survey results between control and HoloLens groups. All subjects within the HoloLens arm saw an increase in their average post-intervention survey score.

Post-intervention, median (range)	4.0 (2-5)	4.5 (2-5)
Z-score (p-value)	-2.04 (0.041) <sup>a</sup>	-1.73 (0.083)
Overall comfort level	4.0 (3-4)	4.0 (3-5)

Scale responses are indicated by 1= strongly disagree, 2= disagree, 3= neither agree nor disagree, 4= agree, 5= strongly agree.

When looking at the individual survey components, the HoloLens cohort reported a significantly improved understanding of the operative steps of the pancreaticoduodenectomy compared to their control counterparts (Table 2). Both cohorts reported a high degree of comfort with proceeding with the planned pancreatoduodenectomy with nearly 75% they were either 'comfortable' or 'very comfortable'.

## **Discussion**

This study is the first of its kind to explore the use of MR technology, specifically the HoloLens, in enhancing the preoperative education of patients undergoing pancreatoduodenectomy. The results indicate that MR can be a valuable tool in improving patient understanding and comfort with surgical procedures, which are critical aspects of the informed consent process.

The use of HoloLens was linked to significant improvements in patient understanding of various aspects of their condition and the surgical procedure. [4] Specifically, HoloLens patients showed a statistically significant increase in their comprehension of the operative steps, potential risks, side effects, and the recovery process. These findings are consistent with previous studies that have demonstrated the efficacy of MR in enhancing learning and retention among medical students. By providing a three-dimensional, interactive visualization of the surgical anatomy and procedure, HoloLens likely aids in bridging the gap between abstract medical information and patient comprehension.

High levels of patient comfort and satisfaction were reported with the use of HoloLens. Nearly 75% of participants across both groups reported feeling either 'comfortable' or 'very comfortable' proceeding with the planned pancreatoduodenectomy. However, those in the HoloLens group expressed greater overall satisfaction. This increased comfort can be attributed to the enhanced clarity and interactivity provided by the MR experience, which likely makes complex medical information more accessible and less intimidating for patients.

Although not objectively quantified, integrating HoloLens into routine clinical practice did not appear to cause significant workflow disruptions in our experience. This suggests that such tools

can be adopted in clinical settings without necessitating major adjustments. This ease of implementation is crucial for the broader application of mixed reality in patient education, as it is a key factor in the adoption of new technologies in healthcare.

## Limitations

While the results are promising, this pilot study has several limitations that must be addressed in future research. The small sample size and single-center design limit the generalizability of the findings. Additionally, the study only included patients who were fluent in English and did not have severe visual or hearing impairments, which may not represent the broader patient population. Future studies should aim to include a more diverse patient cohort to assess the effectiveness of MR across different demographic groups.

Moreover, while the HoloLens group showed significant improvements in specific areas, the overall post-intervention scores between the control and intervention groups did not differ significantly. This suggests that while MR enhances understanding in certain areas, traditional methods also have their merits. Combining MR with traditional educational tools might provide a more comprehensive educational experience. Finally, long-term outcomes related to patient satisfaction and surgical outcomes were not assessed in this study. Future research should explore these aspects to better understand the full impact of MR on patient care.

# Conclusion

This study demonstrates the potential of MR technology to enhance patient education and the informed consent process for complex surgical procedures. MR can play a crucial role in patient-centered care by improving patient understanding and comfort. The successful

160	integration of HoloLens into clinical workflows highlights its feasibility and paves the way for
161	larger, more comprehensive studies to further evaluate its benefits.
